

ences.⁸ The intuition behind instrumentalism is the thought that rationality has something to do with consistency amongst our means and our ends: what an agent has reason to do is take effective means to those ends that she has adopted as her own.⁹ On this picture our ends are supplied by our desires or inclinations, and the question of rationality is about how to satisfy those ends. *Strict instrumentalism* holds that there are no constraints whatsoever on our ultimate ends (or preferences) in choice, and that the only principle of rationality is that we seek these ends. On this view, there are no grounds for the rational criticism of an agent's ends or desires. *Moderate instrumentalism* augments this basic principle with various formal and relational constraints over desires or ends. In particular, moderate instrumentalism can include the view that there are further principles we can use to evaluate or criticize ends.

I will be arguing that strict instrumentalism cannot answer the challenge of temptation. My project is aimed at identifying at least one norm of rational criticism for desires that can be used to show why it is irrational for Kim to act on her temptation to eat the cake. This norm, taken with the Instrumental Principle, will constitute a form of moderate instrumentalism that, I propose, can answer the challenge of temptation. I must point out that my concern in this paper is the narrow problem of temptation generated by hyperbolic discounting, which, with luck and appropriate modifications, could be generalized to other problems.

Let me first specify a few things about instrumentalism. One question that could be asked of the instrumentalist is how she determines what the agent's given ends are. For the purposes of this discussion I am simply going to stipulate that there is a method, and that this method yields what we might intuitively call the 'dominant' desire, where the dominant desire is the one which the agent is most motivated to act on at the time.¹⁰ I take this stipulation to be legitimate in

8 There are (at least) two literatures within which this view is widely discussed. In the literature on practical reason a version of this view often appears in the guise of 'Humean rationality'. See, e.g., Korsgaard, 1997; Railton, 1997; Schroeder, 2004; etc. In the literature on decision theory this view appears in the guise of subjective expected utility theory.

9 This position has been variously presented by both Hare and Broome, among others (Broome, 1999; Hare, 1952).

10 This way of understanding the strength of desires is drawn from what I will call the 'motivational theory of desire'. The motivational theory of desire roughly satisfies the functionalist intuition that mental items are defined by what they characteristically do. Motivation is the characteristic function of desire because it is this action-guiding character that distinguishes desires from beliefs and other mental entities. Each desire has a certain motivational 'push' associated with it. This push is taken to be the measure of how much we are motivated to achieve the associated desire. We can take the felt intensity of a desire to be a type of *prima facie* motivation, but motivation is also the result of deliberation. As we deliberate about questions, in many cases we recruit motivational force to the conclusions of our practical reasoning, namely, our intentions (Schroeder, 2004:11).
